

Environmental Grapevine Physiology and Effects of Climate Change on Grapevine

S. Kaan Kurtural

Introduction

- Grapevine needs a suite of canopy management practices
 - Dormant pruning
 - Green pruning
 - Shoot removal
 - Leaf removal
- Flavonoids and sun exposure
 - May have a beneficial effect

Matus et al. 2009

EXPOSED LEAF AREA

Carbon (CO₂) assimilation

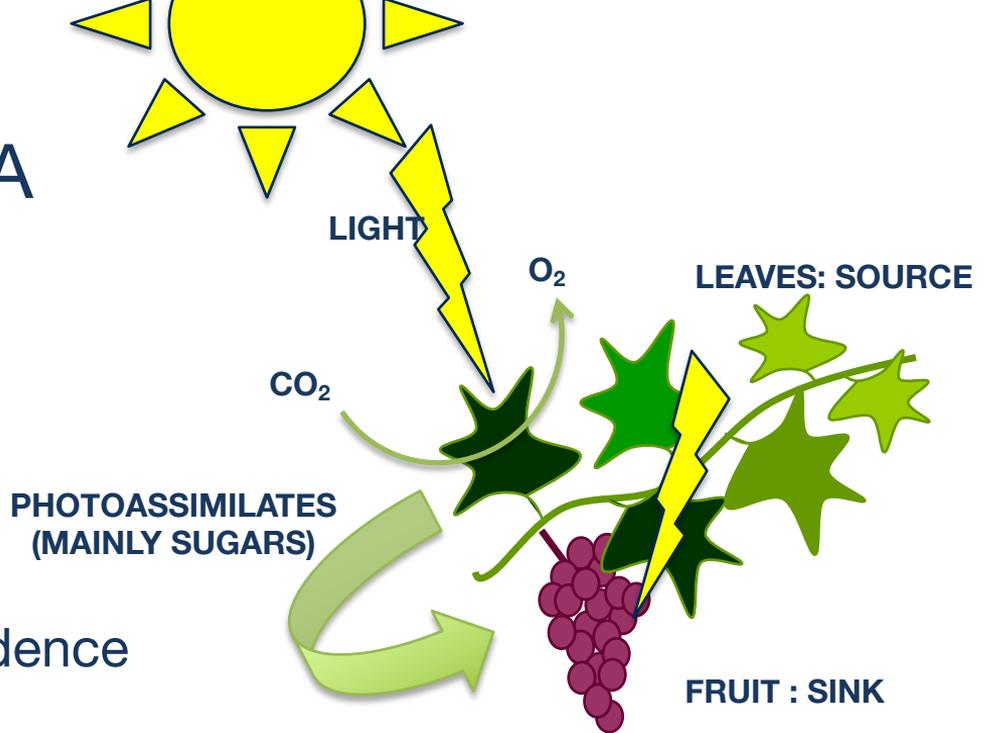

- Ripening
- Yield precursors

Canopy microclimate

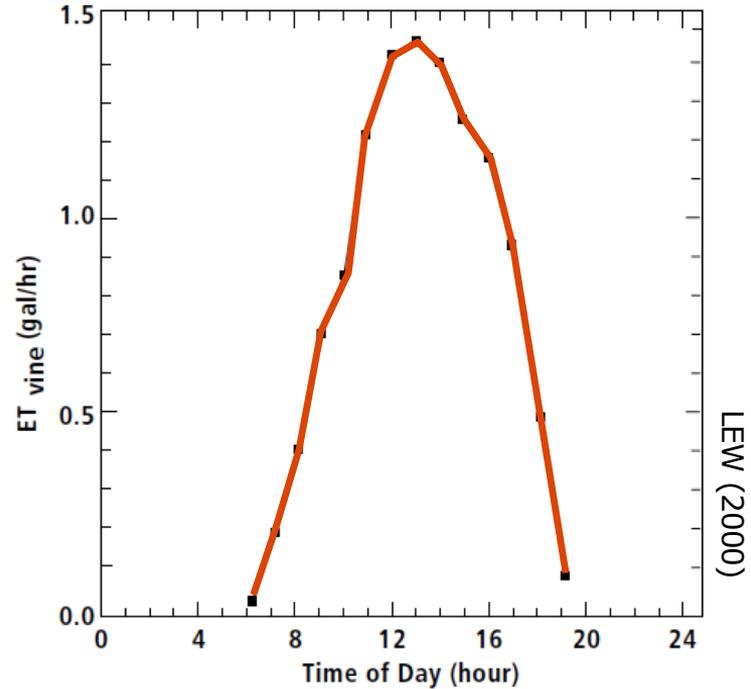

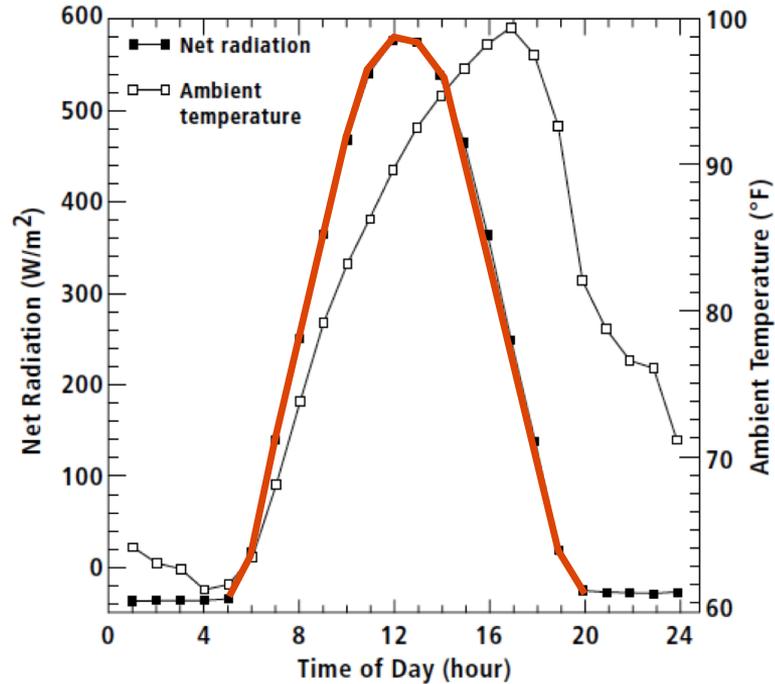

- Fruit composition
- Fungal infection incidence

Irrigation requirements

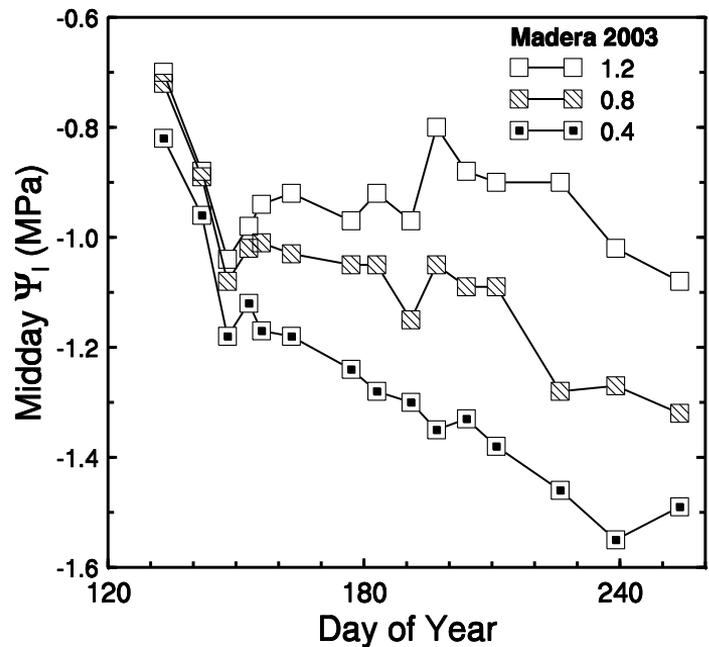

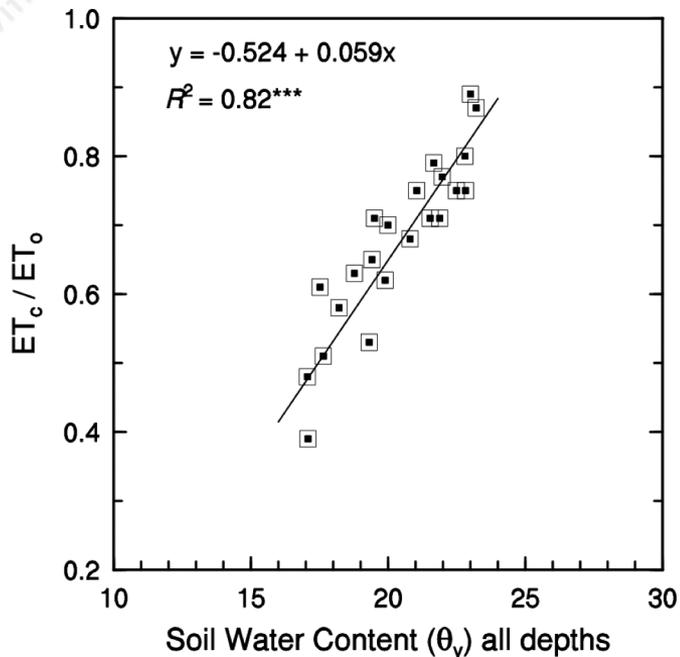

- Leaf area
- Transpiration

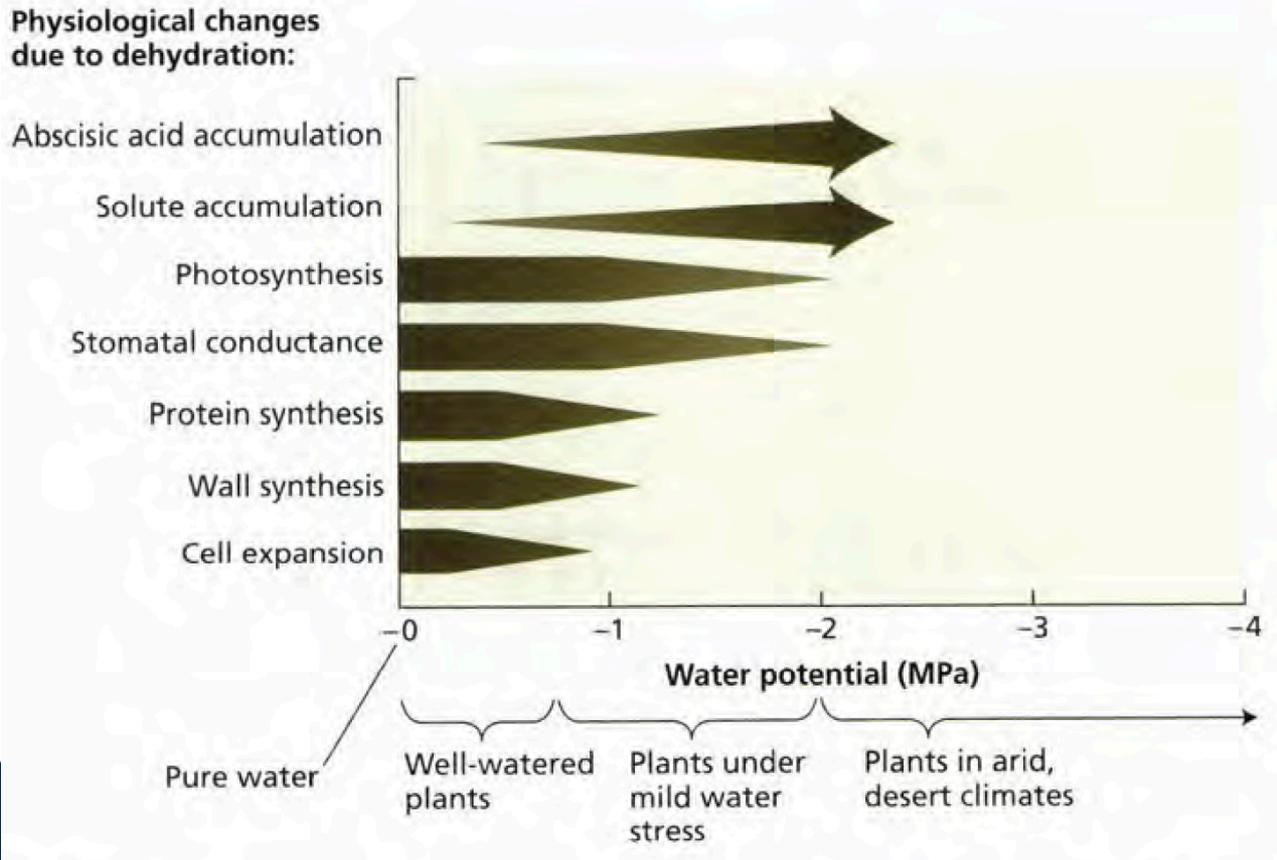

Solar radiation drives vine evapotranspiration

Water use declines with depletion

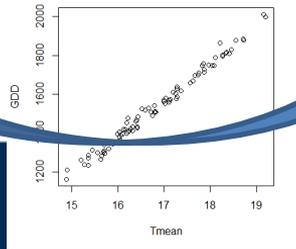

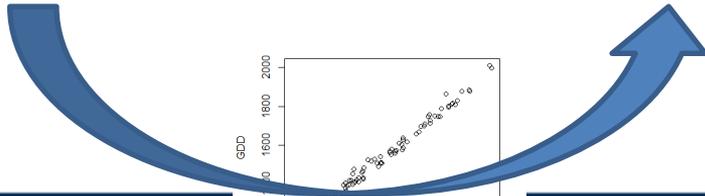

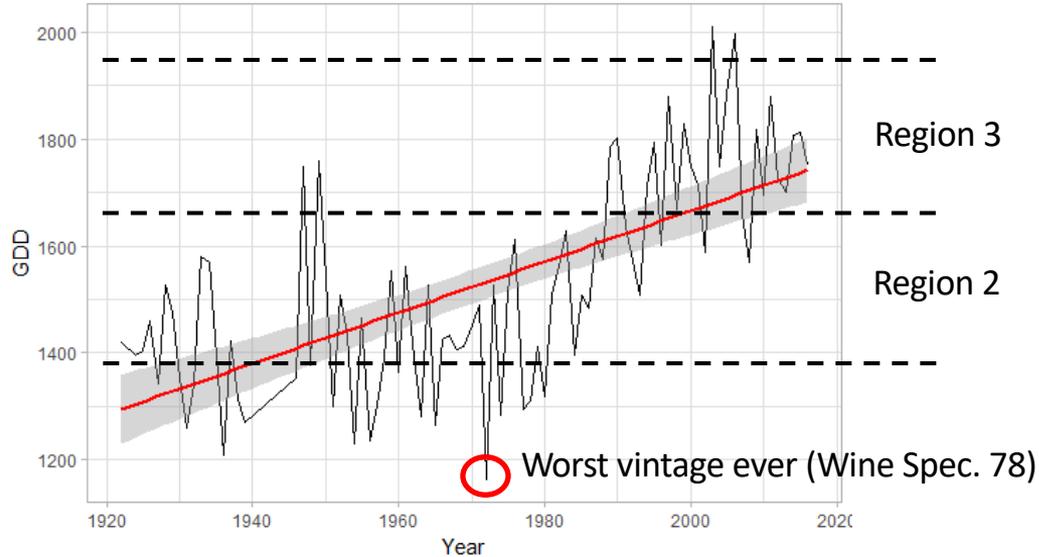

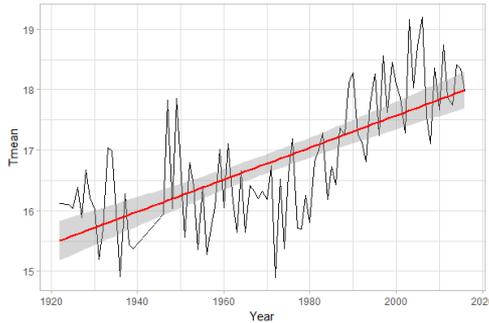

Water deficits affect grapevine physiology

The planet is getting warmer ...and so are Viticulture regions

Napa, CA Temperature

Growing degree days

$$1^{\circ}\text{C} = 1.9^{\circ}\text{F}$$

Heat...the more the better?

Wine Grape quality is an extremely complex topic:

- Subjective
- Gradually changing
- Hundreds of chemical compounds, hard to measure and hard to give a relative importance to each
- Aspects not related to grape quality determining wine price:
Market niche and how much invested in winemaking

...Nobody likes sour grapes

Vintage failure is strongly associated to reaching a certain sugar level

Ribereau-Gayon, P., and G. Guimberteau. Vintage Reports: 1988-1997.

NOAA: Bordeaux Airport meteorological station

Reanalyzed from Jones and Davies 2010 AJEV

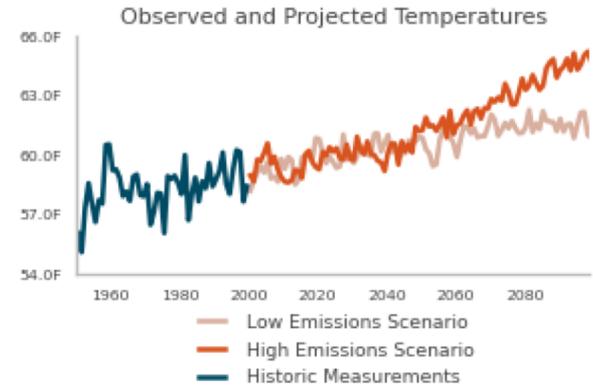

Although temperature is key for sugar. Harvest precocity can be also based on sudden events that force the decision of picking

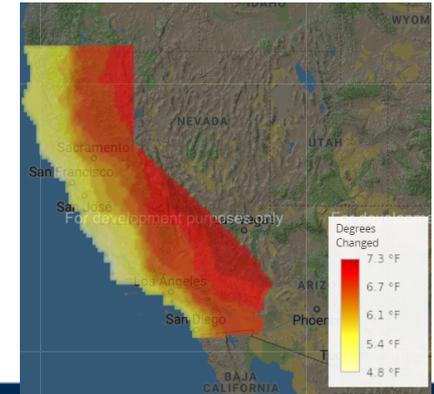

What if it gets warmer?

- Addition of water and tartaric
- Shade nets (kaolin applications did not work for us)
- Breeding efforts for low sugar (INRA and University of Montpellier): 135-150 g/L at ripe stage (max berry vol.)
- IPCC projections:
 - 77% increase of surface burned annually by the end of the century

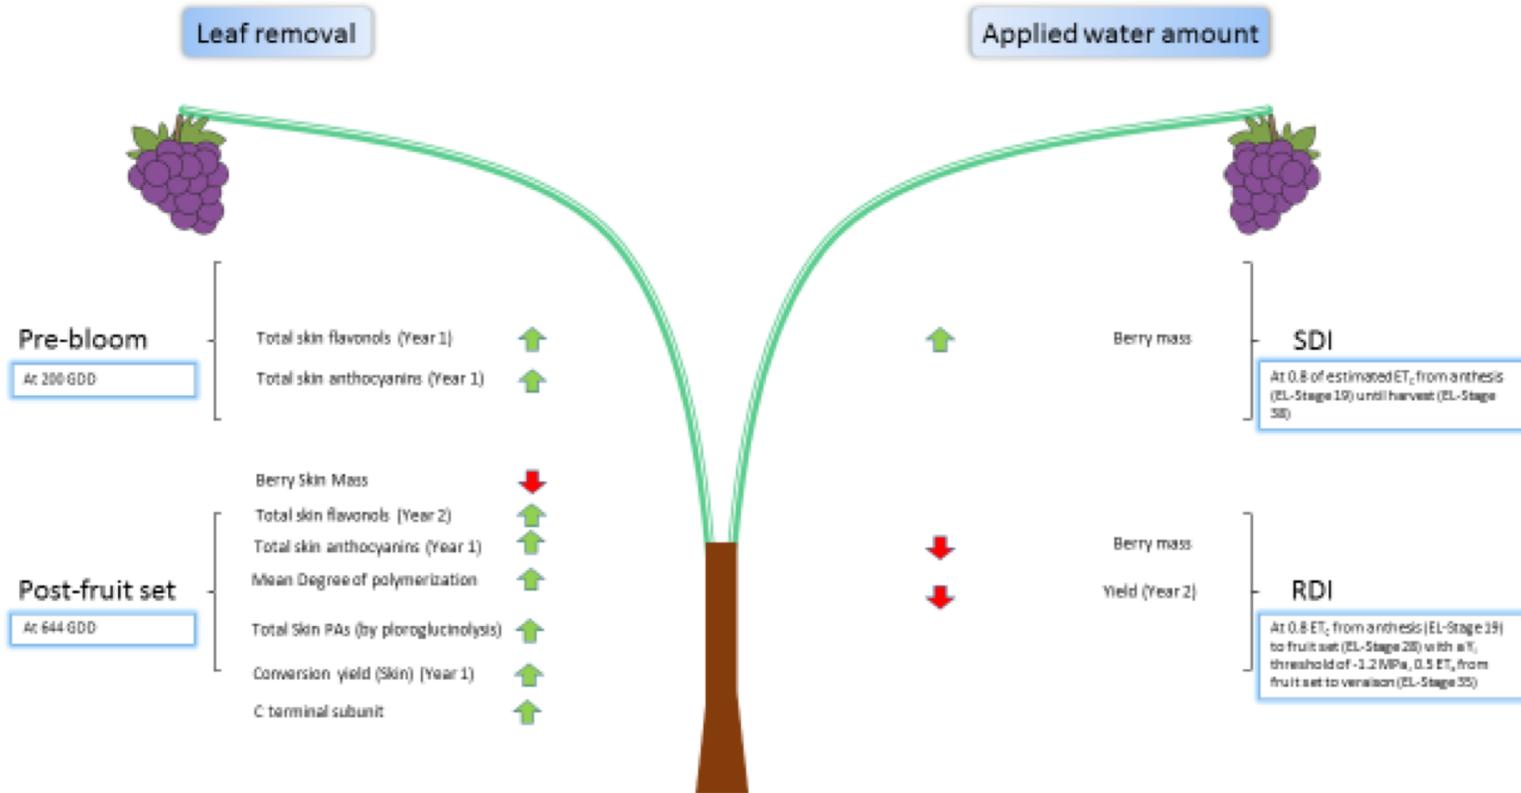

Projections Sta. Helena

SCRIPPS

Previous work in hot climate (Yu et al. 2016 JAgFoodChem)

Experiment

- Randomized complete block
- 3 leaf removal (mechanical)
 - Control
 - Pre-bloom (200 GDD)
 - Post-fruit set (602 GDD)
- 3 applied water amounts
 - 25% ETc
 - 50% ETc
 - 100% ETc (Control)

- Conducted at UC Davis Oakville Experimental Vineyard Napa Co. CA
- Bale loam soil series (USDA 2013)
- Drip-irrigated 4 L/vine/hr system
- Spacing 2.4 m x 2.0 m (row x vine)

Variables monitored

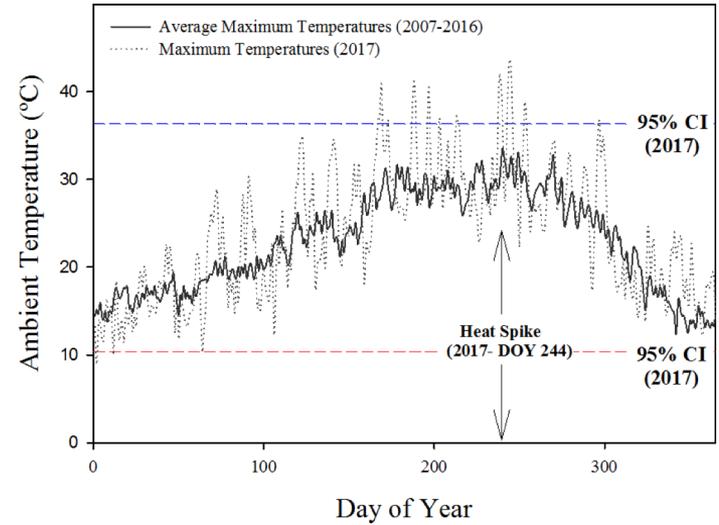

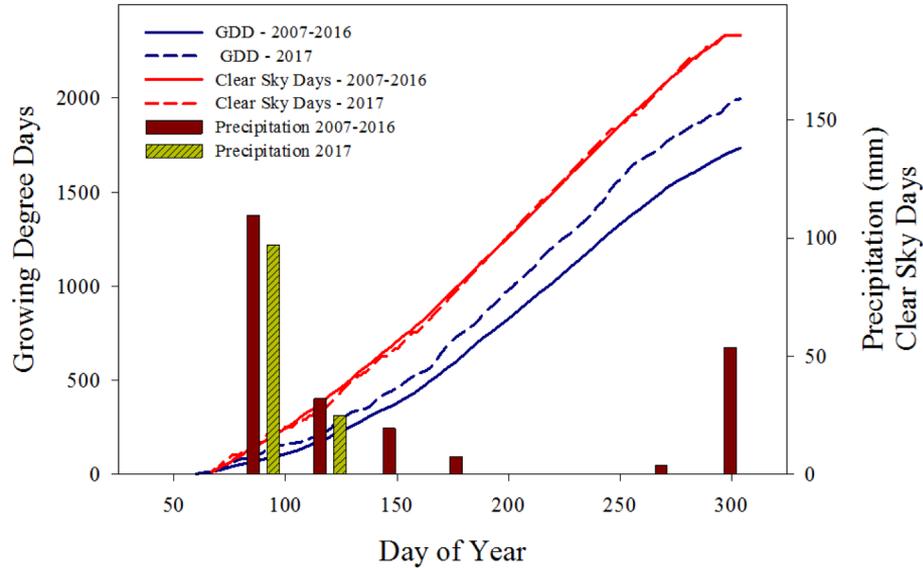

- Primary metabolism
 - Canopy
 - Plant water status
 - Leaf gas exchange
 - Secondary metabolism
 - Flavonols
 - Anthocyanins
 - Proanthocyanidins
- Yield components
Berry chemistry

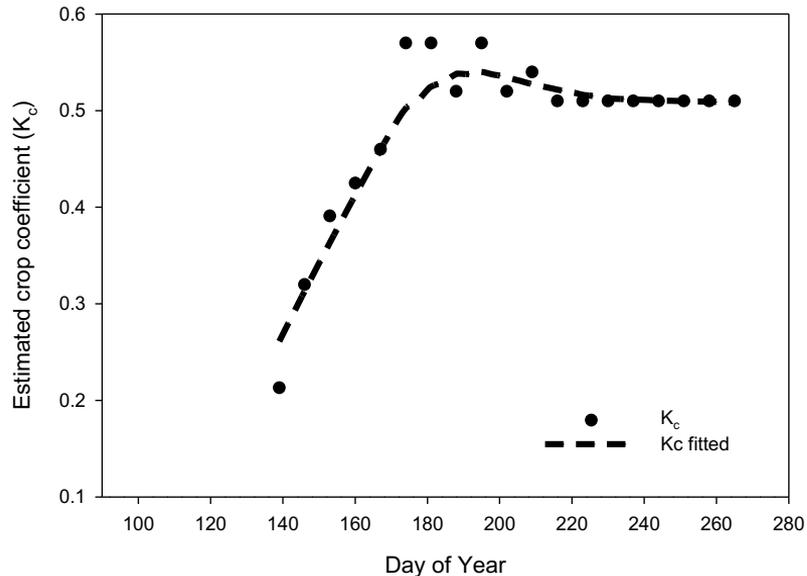

RESULTS

Weather at the experiment site

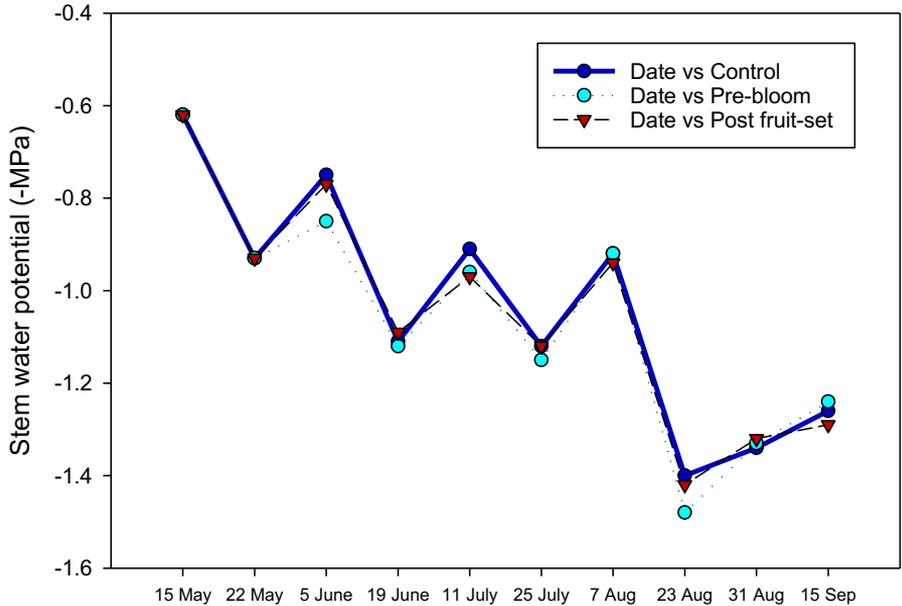

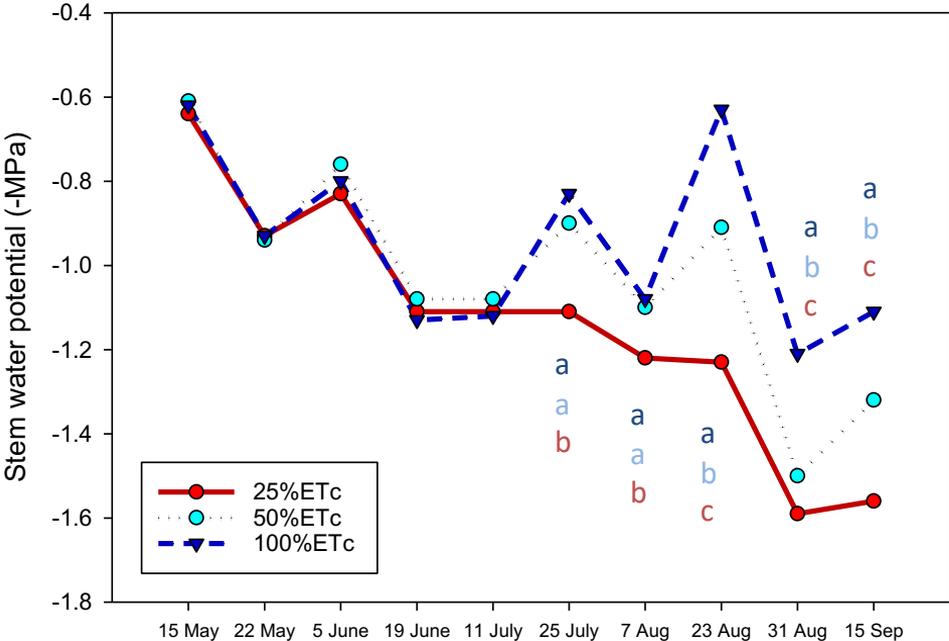

Estimated crop coefficient and applied water amounts

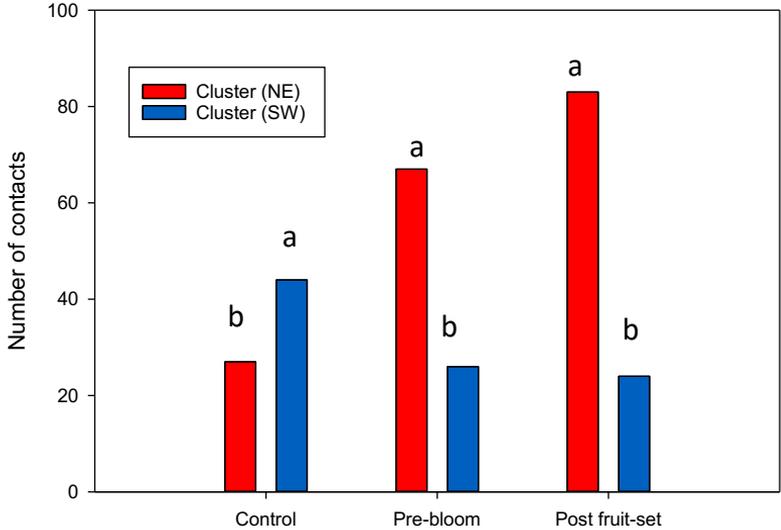

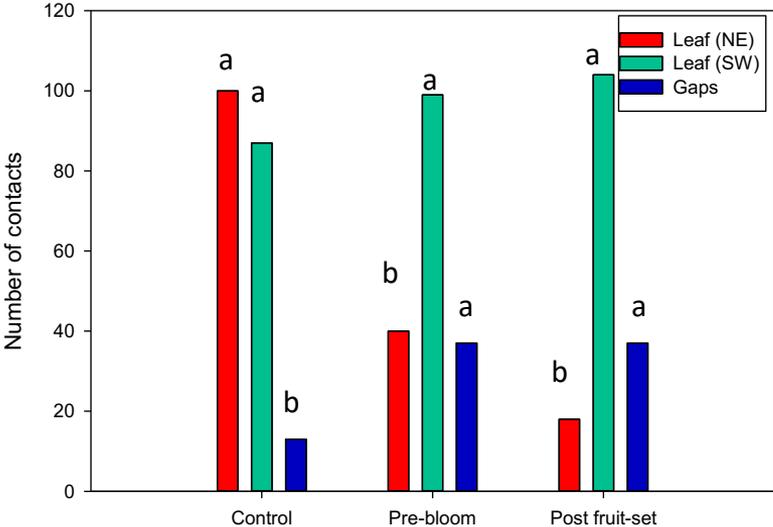

| Phenology stage | Applied water (L/vine) | | |
|--|------------------------|---------|---------|
| | 100% ETc | 50% ETc | 25% ETc |
| Bud-break to fruit set (9 April-31 May) | 187.4 | 93.7 | 46.9 |
| Fruit-set to veraison (31 May-23 July) | 887.4 | 443.7 | 221.9 |
| Veraison to harvest (23 July-12 Sept.) | 810.8 | 405.4 | 202.7 |
| Sum (L/vine) | 1885.7 | 942.8 | 471.4 |

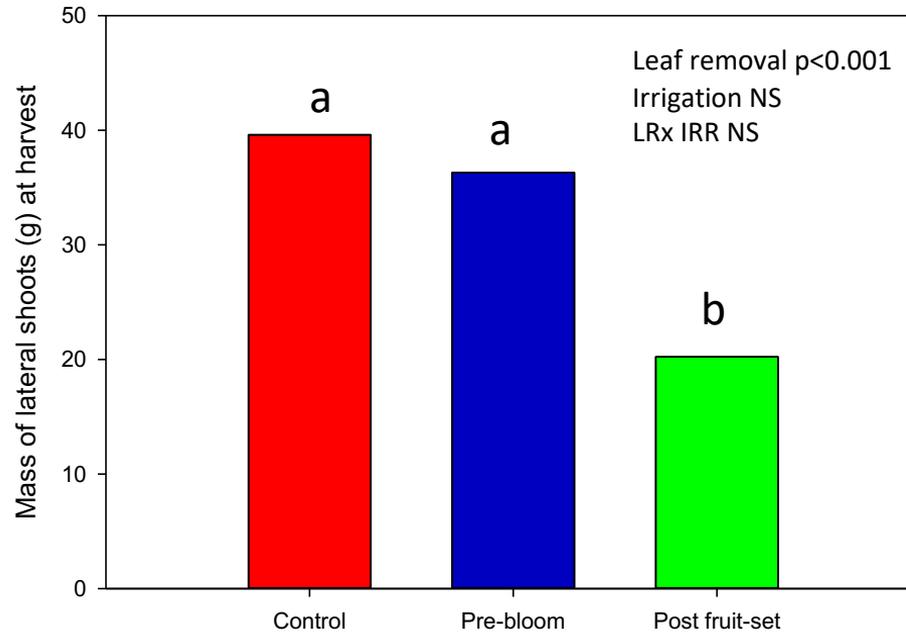

Plant water status

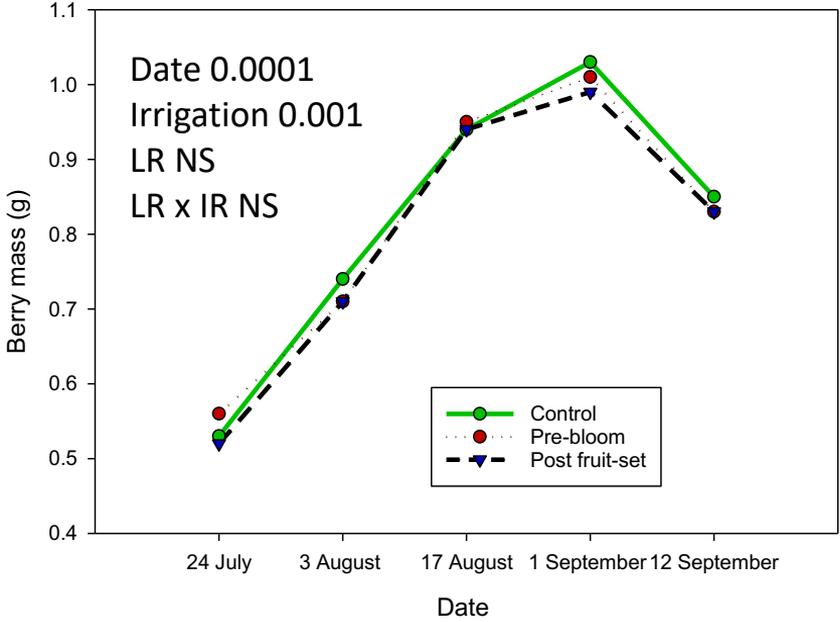

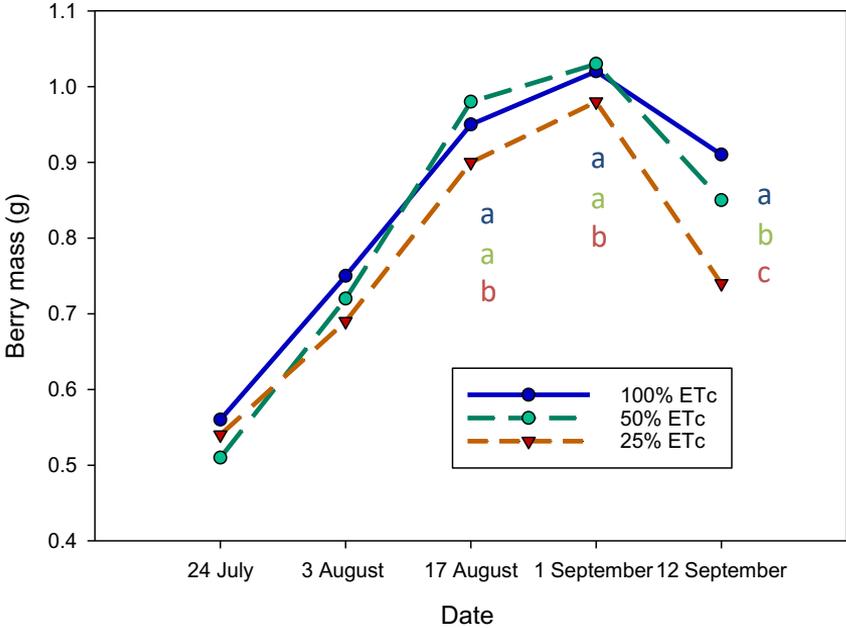

Canopy microclimate at veraison

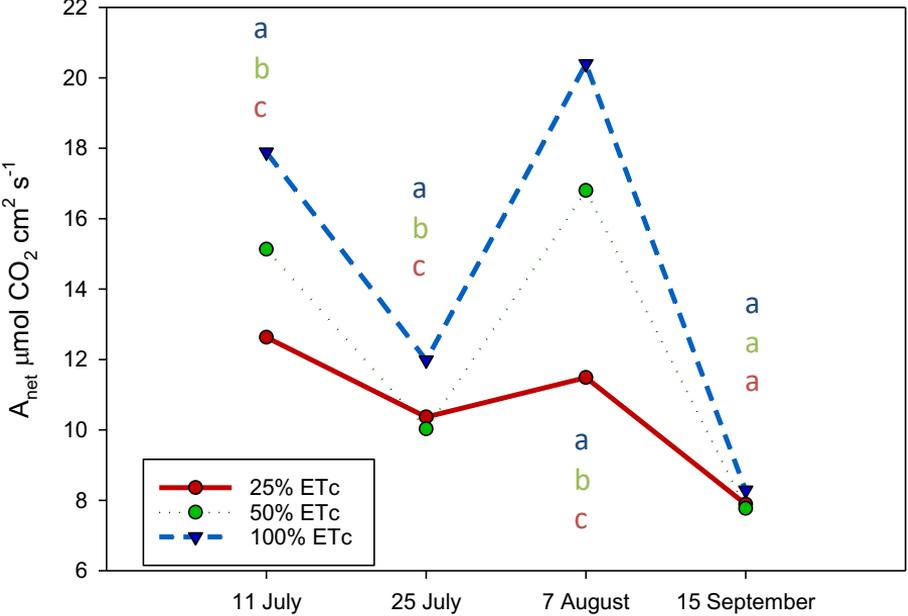

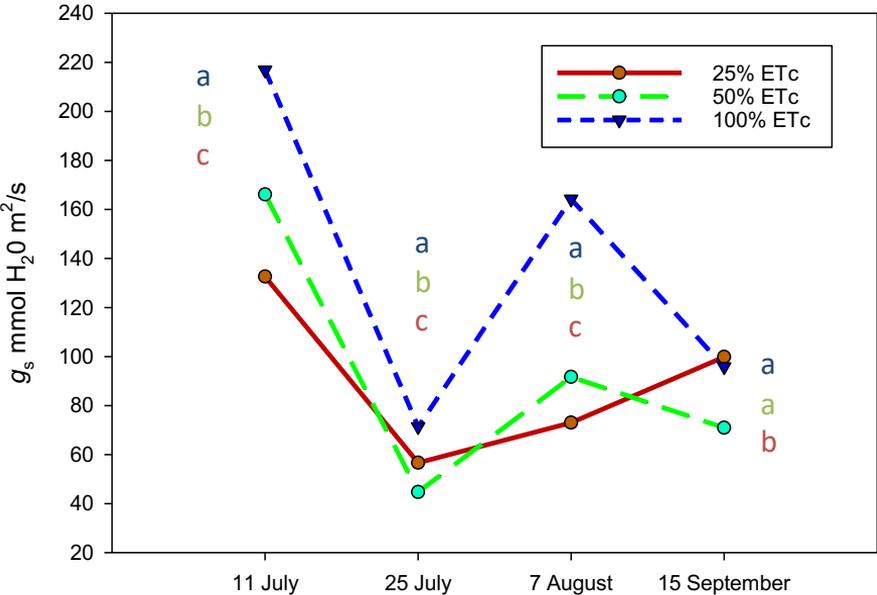

Vegetative compensation of canopy at harvest

PERSPECTIVES

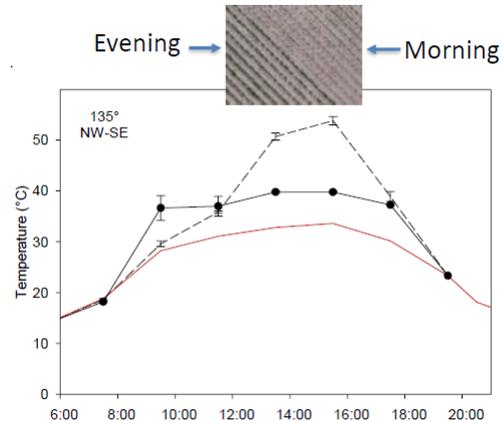

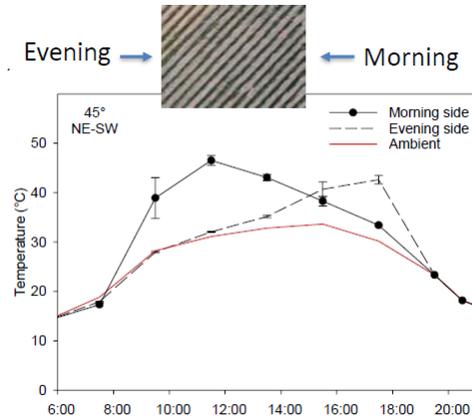

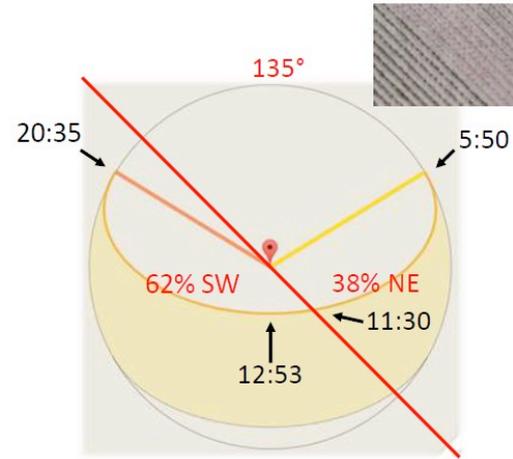

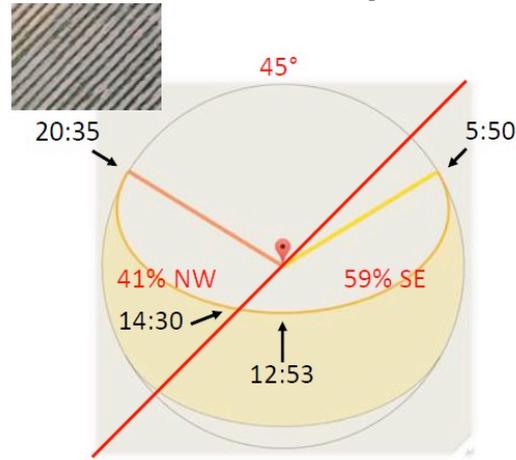

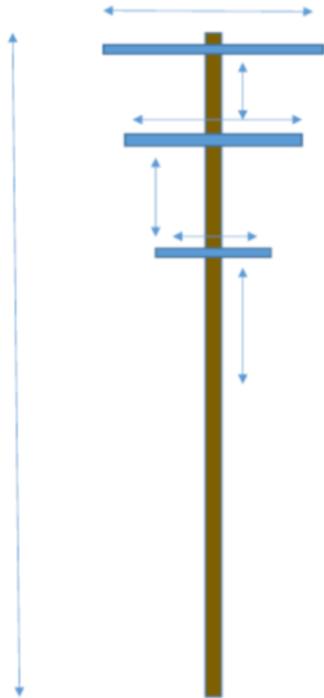

A shifting climate in California's North Coast AVAs

- Little to no cloud cover
- Intermittent heat spikes
- A general warming trend
- No increase in precipitation supply

Shift towards positioned and sprawling systems

The UC Davis 30 Trellis

Primary metabolism summary

- Leaf removal timing
 - No effect on
 - Water status
 - Net gas exchange
 - Components of yield
 - No effect on fruit set
 - Primary metabolites
- Applied water amounts
 - Significant effect on
 - Water status
 - Net gas exchange
 - Components of yield
 - Primary metabolites
 - Only TSS

Applied water amounts

SEVERITY

TIME AND DURATION

Water deficits

INDIRECT EFFECT

↓ Berry mass
↑ Ratio of skin to pulp

↑ Concentration of ANTHOCYANINS
↑ Concentration en FLAVONOLS
Minor effect on Proanthocyanidins

Canopy modification

Ameliorated fruit zone exposure

↑ FLAVONOL biosynthesis

DIRECT EFFECT

Stimulation of anthocyanin biosynthesis ↔ Gene activation

3OH forms of anthocyanins are favored

↑ ANTHOCYANINS

Canopy manipulation

Leaf Removal (Early or Late)

↑ Solar radiation exposure of berry

Excessive temperature (> 37°C berry temperature)

Light and temperature

Adaptive mechanism

Impact of light

Anthocyanin degradation

Biosynthesis of anthocyanins

↑ Berry skin mass

FLS enzyme (flowering to veraison)

↑ LAR and BAN

↑ ANTHOCYANINS

↑ FLAVONOLS

↑ PROANTHOCYANIDINS

COLOR STABILITY in RED WINE

ASTRINGENCY

Conclusions

- Cluster microclimate without leaf removal already optimized
- Clear skies, long periods with minimal precipitation coupled with irrigation restriction have stronger effect on primary and secondary metabolism than canopy manipulation (e.g. shoot or leaf removal)
 - An optimal ET replacement is 50%-60% ET_c using sustained deficits.
- Although not as impactful, there seems to be interest from producers to understand the impact of leaf removal practices on berry physiology
